## **k9: Manual**

This document explains the usage of the k9 programming language in very simple terms and is intended for newbies only.

# 1 Intro

Shakti, aka k9, is a programming language built for speed, consice syntax, and data manipulation. The syntax is a bit special and although it might feel like an impediment at first becomes an advantage with use.

The k9 language is more closely related to mathematics syntax than most programming lanauges. It requires the developer to learn to speak k9 but once that happens most find an ability to “speak” quicker in k9 than in other languages. At this point an example might help.

In mathematics, “3+2” is read as “3 plus 2” as you learn at an early age that “+” is the “plus” sign. For trival operations like arithmetic most programming languages use symbols also. Moving on to something less math like most programming lanauges switch to clear words while k9 remains with symbols which turn out to have the same level of clarity. As an example, to determine the distinct values of a list most programming languages might use a synatx like `distinct()` while k9 uses `?`. This requires the developer to learn how to say a number of symbols but once that happens it results in much shorter code that is quicker to write, harder to bug, and easier to maintain.

In math which do you find easier to answer?

Math with text

Three plus two times open parenthesis six plus fourteen close parenthesis

Math with symbols

$3+2*(6+14)$

In code which do you find easier to understand?

Code with text

```
x = (0,12,3,4,1,17,-5,0,3,11);y=5;
distinct_x = distinct(x);
gt_distinct_x = [i for i in j if i >= y];
```

Code with symbols

```
x:(0,12,3,4,1,17,-5,0,3,11);y:5;
z@&y<z:?x
```

If you’re new to k9 and similar languages, then you should likely appreciate symbols is shorter but looks like line noise. That’s true but so did arithmetic until you learns the basics.

When you first learned arithmetic you likley didn’t have a choice. Now you have a choice about learning k9. If you give it a try, then I expect you’ll get it quickly and move onto the power phase fast enough that you’ll be happy you gave it a chance.

## 1.1 Get k9.

<https://shakti.com/>

Go to the Shakti website and click on download. You'll need to enter a few pieces of information and then you'll have a choice to download either a Linux or MacOS version. Click on the required OS version and you'll download a `k.zip` file around 50 kb in size. Unzip that file and you'll have a single executable file `k` which is the language.

## 1.2 rlwrap

Although you only need the `k` binary to run `k9` most will also install `rlwrap`, if not already installed, in order to get command history in a terminal window. `rlwrap` is “Readline wrapper: adds readline support to tools that lack it” and allows one to arrow up to go through the command buffer generally a useful option to have.

In order to start `k9` you should either run `k` or `rlwrap k` to get started. Here I will show both options but in generally one would run as needed. In this document lines with input be shown with a leading space and output will be without. In the examples below the user starts a terminal window in the directory with the `k` file. Then the users enters `rlwrap ./k RET`. `k9` starts and displays the date of the build, (c), and shakti and then listens to user input. In this example I have entered the command to exit `k9`, `//`. Then I start `k9` again without `rlwrap` and again exit the session.

```
rlwrap ./k
2020.04.01 (c) shakti
//

./k
2020.04.01 (c) shakti
//
```

## 1.3 Simple example

Here I will start up `k9`, perform some trivial calculations, and then close the session. After this example it will be assumed the user will have a `k9` session running and working in repl mode. Comments (`/`) will be added to the end of lines as needed.

```
rlwrap ./k
2020.04.01 (c) shakti
n:10000 / n data points
s:`a`b`c / data for symbols a, b, and c
q:+s!(-1+n?2;-1+n?2;-1+n?2) / table of returns (-1,0,1) for each symbol
q / print out the table
a b c
-- -- --
0 1 1
-1 -1 0
-1 1 1
0 1 -1
-1 -1 -1
..
```

At this point you might want to check which symbol has the highest return, most variance, or any other analysis on the data.

```

#'=q                                / count each unique a/b/c combination
a  b  c |
-- -- --|---
  0  1  1|407
-1 -1 -1|379
-1  0  0|367
  0 -1 -1|391
  1  1  1|349
..
-1#+\q                                / calculate the return of each symbol
a    b    c
--- --- --
-68 117 73
{(+/m*m:x-avg x)%#x}' +q            / calculate the variance of each symbol
a|0.6601538
b|0.6629631
c|0.6708467

```

## 1.4 Document formatting for code examples

This document uses a number of examples to help clarify k9. The syntax is that input has a leading space and output does not. This follows the terminal syntax where the REPL input has space but prints output without.

```

3+2 / this is input
5    / this is output

```

## 1.5 k9 nuances

One will need to understand some basic rules of k9 in order to progress. These will likely seem strange at first.

### 1.5.1 : is used to set a variable to a value

`a:3` is used to set the variable, `a`, to the value, `3`. `a=3` is an equality test to determine if `a` is equal to `3`.

### 1.5.2 % is used to divide numbers

Yeah, `2 divide by 5` is written as `2%5` and not `2/5`.

### 1.5.3 Evaluation is done right to left

`2+5*3` is 17 and `2*5+3` is 16. `2+5*3` is first evaluated on the right most portion, `5*3`, and once that is computed then it proceeds with `2+15`. `2*5+3` goes to `2*8` which becomes 16.

### 1.5.4 There is no arithmetic order

`+` does not happen specially before or after `*`. The order of evaluation is done right to left unless parenthesis are used. `(2+5)*3 = 21` as the `2+5` in parenthesis is done before being multiplied by 3.

### 1.5.5 Operators are overloaded depending on the number of arguments.

```

*(3;6;9)    / single argument so * is first element of the list
3
2*(3;6;9)   / two arguments so * is multiplication
6 12 18

```

### 1.5.6 Lists and functions are very similar.

k9 syntax encourages you to treat lists and functions in a similar function. They should both be thought of a mapping from a value to another value or from a domain to a range.

```

1:3 4 7 12
f:{3+x*x}
l@2
7
f@2
7

```

### 1.5.7 k9 is expressed in terms of grammar.

k9 uses an analogy with grammar to describe language syntax. The k9 grammar consists of nouns (data), verbs (functions) and adverbs (function modifiers).

- The boy ate an appple. (Noun verb noun)
- The girl ate each olive. (Noun verb adverb noun)

In k9 as the Help/Info card shows data are nouns, functions/lists are verbs and modifiers are adverbs.

- 3 > 2 (Noun verb noun)
- 3 >' 0 1 2 3 4 5 (Noun verb adverb noun)

## 1.6 Help/Info Card

Typing `\` in the terminal gives you a concise overview of the language. This document aims to provide details to beginning users where the help screen is a tad too terse.

```
\
$ k a.k

Verb      Adverb      Noun      Type      System
: set      ' each      i bar      bool 110b      b \l a.k
+ plus      flip        / over/right i div      int 2 3 4      i *\d [d]
- minus      negate      \ scan/left i mod      flt 2e3 0N 0W      f \v [d]

```

## 2 Data / Nouns

The basic data types of the k9 language are numbers (integer and float), text (characters and enumerated/name) and temporal (date and time). It is common to have functions operate on multiple data types.

In addition to the basic data types, data can be put into lists (uniform and non-uniform), dictionaries (key-value pairs), and tables (transposed/flipped dictionaries). Dictionaries and tables will be covered in a separate chapter.

Data types can be determined by using the `@` function on values or lists of values. In the case of lists `@` returns the type of the list ``L` but the function can be modified to evaluate each type `@'` instead and return the type of each element in the list.

```
@(3;3.1;"b";`a;12:01:02.123;2020.04.05)
`L
@'(3;3.1;"b";`a;12:01:02.123;2020.04.05)
`i`f`c`s`t`D
```

### 2.1 Numeric Data Types

Numbers can be stored as integers and floats.

```
@3
@3.1
`f
a:3;b:3.1;
@a
`i
@b
`f
```

Numeric data can be recast as other types using the `$` command. The `$` is an overloaded function and can either convert to string or cast to type if provided. The first usage takes only a single argument, the item to be converted to a string, while the second usage takes two arguments, the items to be converted and also the type to convert into.

You'll note that the string of 3 is represented as `,3`. The comma represents the string is a list of length one and not a single element.

```
$3      / convert to string
,"3"
$12     / convert to string
"12"
`f$12   / convert to float
12f
`t$12   / convert to time
00:00:00.012
`d$12   / convert to date
2024-01-13
```

## 2.2 Extreme values

Data types can not only represent in-range values but also null and out-of-range values.

<b>type</b>	<b>null</b>	<b>out of range</b>
i	0N	0W
f	0n	0w

## 3 Functions / Verbs

This chapter explains all functions, aka verbs. Most functions are overloaded and change depending on the number and type of arguments.

Verb

```
: (*note set::)
+ (*note plus::)      (*note flip::)
- (*note minus::)     (*note negate::)
* (*note times::)     (*note first::)
% (*note divide::)
& (*note min::)       (*note where::)
| (*note max::)       (*note reverse::)
< (*note less::)      (*note asc::)
> (*note more::)      (*note dsc::)
= (*note equal::)     (*note group::)
~ (*note match::)     (*note not::)
! (*note key::)       (*note enum::)
, (*note cat::)       (*note enlist::)
^ (*note cut::)       (*note sort::)
$ (*note cast::)      (*note string::)
# (*note take::)      (*note count::)
_ (*note drop::)      (*note floor::)
? (*note find::)      (*note unique::)
@ (*note at::)        (*note type::)
. (*note apply::)     (*note value::)
```

### 3.1 set $\Rightarrow$ x:y

Set a variable, x, to a value, y.

```
a:3
a
3
b:(`green;37;"blue)
b
green
37
blue
c:{x+y}
c
{x+y}
c[12;15]
27
```

### 3.2 plus $\Rightarrow$ x+y

Add x and y.

```
3+7
```

```

10
  a:3;
  a+8
11
  3+4 5 6 7
7 8 9 10
  3 4 5+4 5 6
7 9 11
  3 4+1 2 3 / lengths don't match, will error: length
error: length
  10:00+1      / add a minute
10:01
  10:00:00+1   / add a second
10:00:01
  10:00:00.000+1 / add a millisecond
10:00:00.001

```

### 3.3 flip $\Rightarrow$ +x

Flip, or transpose, x.

```

  x:((1 2);(3 4);(5 6))
  x
1 2
3 4
5 6
+x
1 3 5
2 4 6
`a`b!+x
a|1 3 5
b|2 4 5
+`a`b!+x
a b
- -
1 2
3 4
5 6

```

### 3.4 minus $\Rightarrow$ x-y

Subtract y from x.

```

  5-2
3
  x:4;y:1;
  x-y
3

```

**3.5 negate  $\Rightarrow$  -x**

Negative x.

```
-3
-3
--3
3
x:4;
-x
-4
d:`a`b!((1 2 3);(4 5 6))
-d
a|-1 -2 -3
b|-4 -5 -6
```

**3.6 times  $\Rightarrow$  x\*y**

Mutlply x and y.

```
3*4
12
3*4 5 6
12 15 18
1 2 3*4 5 6
4 10 18
```

**3.7 first  $\Rightarrow$  \*x**

Return the first value of x.

```
*1 2 3
1
*((1 2);(3 4);(5 6))
1 2
**((1 2);(3 4);(5 6))
1
*`a`b!((1 2 3);(4 5 6))
1 2 3
```

**3.8 divide  $\Rightarrow$  x%y**

Divide x by y.

```
12%5
2.4
6%2    / division of two integers returns a float
3f
```

**3.9 min  $\Rightarrow$  x&y**

The smaller of x and y.

```

3&2
2
1 2 3&4 5 6
1 2 3
010010b&111000b
010000
`a&`b
`a

```

### 3.10 where $\Rightarrow$ &x

Given a list of integer values, eg. x\_0, x\_1, ..., x\_(n-1), generate x\_0 values of 0, x\_1 values of 1, ..., and x\_(n-1) values of n-1.

```

& 3 1 0 2
0 0 0 1 3 3
&001001b
2 5
"banana"="a"
010101b
&"banana"="a"
1 3 5
x@&30<x:12.7 0.1 35.6 -12.1 101.101 / return values greater than 30
35.6 101.101

```

### 3.11 max $\Rightarrow$ x|y

The greater of x and y.

```

3|2
3
1 2 3|4 5 6
4 5 6
101101b|000111b
101111b

```

### 3.12 reverse $\Rightarrow$ |x

Reverse the list x.

```

|0 3 1 2
2 1 3 0
|"banana"
"ananab"
|((1 2 3);4;(5 6))
5 6
4
1 2 3

```

**3.13 less  $\Rightarrow$  x < (>) y**

x less (more) than y.

```

3<2
0b
2<3
1b
1 2 3<4 5 6
111b
((1 2 3);4;(5 6))<((101 0 5);12;(10 0)) / size needs to match
101
1
10
"a"<"b"
1b

```

**3.14 up  $\Rightarrow$  < (>) x**

The indices of a list in order to sort the list in ascending (descending) order.

```

<2 3 0 12
2 0 1 3
x@<x:2 3 0 12
0 2 3 12

```

**3.15 equal  $\Rightarrow$  x=y**

x equal to y

```

2=2
1b
2=3
0b
"banana"="abnaoo"
001100b

```

**3.16 group  $\Rightarrow$  =x**

A dictionary of the distinct values of x (key) and indices (values).

```

="banana"
a|1 3 5
b|0
n|2 4
=0 1 0 2 10 7 0 1 12
0|0 2 6
1|1 7
2|3
7|5
10|4
12|8

```

**3.17 match  $\Rightarrow$  x~y**

Compare x and y.

```
2~2
1b
2~3
0b
`a`b~`a`b / different than = which is element-wise comparison
1b
`a`b=~a`b
11b
```

**3.18 not  $\Rightarrow$  ~x**

Boolean invert of x

```
~1b
0b
~101b
010b
~37 0 12
010b
```

**3.19 key  $\Rightarrow$  x!y**

Dictionary of x (key) and y (value)

```
3!7
,3!,7
`a`b!3 7
a|3
b|7
`a`b!((1 2);(3 4))
a|1 2
b|3 4
```

**3.20 enum  $\Rightarrow$  !x**

Generate an integer list from 0 to x-1.

```
!3
0 1 2
```

**3.21 cat  $\Rightarrow$  x,y**

Concatenate x and y.

```
3,7
3 7
"hello"," ","there"
"hello there"
```

**3.22 enlist  $\Rightarrow$  ,x**

Create a list from x

```
,3
,3
,1 2 3
1 2 3
3=,3
,1b
3~,3
0b
```

**3.23 cut  $\Rightarrow$  x<sup>y</sup>**

Reshape a list y by indices x.

```
0 1 5^0 1 2 3 4 5 6 7 8 9
0
1 2 3 4
5 6 7 8 9
1 5^0 1 2 3 4 5 6 7 8 9
1 2 3 4
5 6 7 8 9
```

**3.24 asc  $\Rightarrow$  ^x**

Sort list x into ascending order.

```
^0 3 2 1
0 1 2 3
^^b^a!((0 1 2);(7 6 5)) / sort dictionary by key
a|7 6 5
b|0 1 2
```

**3.25 cast  $\Rightarrow$  x\$y**

Cast y into type x.

```
`i$37.1 37.9
37 37
`f$3
3f
`D$"2020.03.01"
2020-03-01
`t$123
00:00:00.123
```

**3.26 string  $\Rightarrow$  \$x**

Cast x to string.

```
$`abc`d
```

```
abc
d
$4.7
"4.7"
```

### 3.27 take $\Rightarrow$ x#y

First (last) x elements of y if x is positive (negative). If x is a list then returns any values in both x and y.

```
3#0 1 2 3 4 5          / first three
0 1 2
-3#0 1 2 3 4 5         / last three
3 4 5
2#"hello"
"he"
(1 2 3 7 8 9)#(2 8 20) / union
2 8
```

### 3.28 count $\Rightarrow$ #x

Count the number of elements in x.

```
#0 1 2 12
4
#((0 1 2);3;(4 5))
3
#a`b!((1 2 3);(4 5 6)) / count the number of keys
2
```

### 3.29 drop $\Rightarrow$ x\_y

Return the list y without the first (last) x elements if x is positive (negative). If x is a list then returns any values from y not in x.

```
3_0 1 2 3 4 5
3 4 5
-3_0 1 2 3 4 5
0 1 2
a:3;b:0 9 1 8 2 7;
a_b
8 2 7
(1 2 3 7 8 9)_(2 8 20)
,20
```

### 3.30 find $\Rightarrow$ x?y

Find the first element of x that matches y otherwise return the end of vector.

```
`a`b`a`c`b`a`a?`b
1
`a`b`a`c`b`a`a?`d
```

```

7
  0 1 2 3 4?10
5
  (1;`a;"blue";7.4)?3
4

```

### 3.31 unique $\Rightarrow$ ?x

Return the unique values of the list x. The ? preceeding the return value explicitly shows that list has no repeat values.

```

  ?`f`a`b`c`a`b`d`e`a
?`f`a`b`c`d`e
  ?"banana"
?"ban"

```

### 3.32 at $\Rightarrow$ x@y

Given a list x return the value(s) at index(indices) y.

```

  (3 4 7 12)@2
7
  `a`b`c@2
`c
  ((1 2);3;(4 5 6))@(0 1)  / values at indices 0 and 1
1 2
3

```

### 3.33 type $\Rightarrow$ @x

Return the data type of x.

```

  @1
  `i
  @1.2
  `f
  @`a
  `s
  @"a"
  `c
  @2020.04.20
  `D
  @12:34:56.789
  `t
  @(1;1.2;`a;"a";2020.04.20;12:34:56.789)  / type of a list
  `L
  @'(1;1.2;`a;"a";2020.04.20;12:34:56.789) / type of elements of the list
  `i`f`s`c`D`t

```

**3.34 apply  $\Rightarrow$  x.y**

Given list x return the value at index list y.

```
(3 4 7 12).,2
7
`a`b`c.,2
`c
((1 2);3;(4 5 6)).(0 1) / value at index 0 and then index 1
2
```

**3.35 value  $\Rightarrow$  .x**

Return the value of dictionary x as lists.

```
`a`b!(1 2;3 4)
a|1 2
b|3 4
.`a`b!(1 2;3 4)
a    b
1 2 3 4
```

## 4 Function Modifiers / Adverbs

k9 uses function modifiers / adverbs in order to have functions operate iteratively over lists.

### 4.1 each $\Rightarrow$ f'x

Apply each value in list x to function f.

```

*((1 2 3);4;(5 6);7) / first element of the list
1 2 3
*'((1 2 3);4;(5 6);7) / first element of each element
1 4 5 7

```

### 4.2 bar $\Rightarrow$ x'y

x divided by y using integer division and then multiplied by x. x is an integer and y is a list of integers.

```

5'0 1 2 3 4 5 9 10
0 0 0 0 0 5 5 10

```

### 4.3 scan $\Rightarrow$ (f\ )x

Create values for each x according to...

- f@0  $\rightarrow$  x@0
  - f@1  $\rightarrow$  f[f@0;x@1]
  - ...
  - f@i  $\rightarrow$  f[f@i-1;x@i]
  - ...
  - f@n  $\rightarrow$  f[f@n-1;x@n]
- ```

(,\)("a";"b";"c")
a
ab
abc
(+\)1 20 300
1 21 321
({y+10*x}\)1 20 300
1 30 600

```

### 4.4 left $\Rightarrow$ f\[x;y]

Apply f[y] to each value in x.

```

{x+y}[100 200 300;1 2 3] / add the lists together itemize
101 202 303
{x+y}\[100 200 300;1 2 3] / add the list y to each value of x
101 102 103
201 202 203

```

```

301 302 303
  {x,y}\[`l1`l2`l3;`r1`r2`r3]
11 r1 r2 r3
12 r1 r2 r3
13 r1 r2 r3

```

#### 4.5 mod $\Rightarrow$ x\y

The remainder after y divided by x using integer division. x and y must be integers.

```

12\27
3
5\22
2

```

#### 4.6 over $\Rightarrow$ (f/)x

Same as scan but only print last value.

```

(,/)("a";"b";"c")
"abc"
(+/)1 20 300
321
({y+10*x}/)1 20 300
600

```

#### 4.7 right $\Rightarrow$ f/[x;y]

Apply f[x;] to each value in y.

```

{x+y}[100 200 300;1 2 3] / add the lists together itemize
101 202 303
{x+y}/[100 200 300;1 2 3] / add the list y to each value of x
101 201 301
102 202 302
103 203 303
{x,y}/[`l1`l2`l3;`r1`r2`r3]
11 12 13 r1
11 12 13 r2
11 12 13 r3

```

#### 4.8 div $\Rightarrow$ x/y

y divided by x using integer division. x and y must be integers.

```

2/7
3
22/5
4

```

## 4.9 each prior $\Rightarrow$ f':[x;y]

Apply f[y\_n;y\_{n-1}]. f\_0 is a special case of f[y\_0;x].

```
,':[`x;(`$"y",'$!5)]
y0 x
y1 y0
y2 y1
y3 y2
y4 y3
%':[100;100 101.9 105.1 102.3 106.1] / compute returns
1 1.019 1.031403 0.9733587 1.037146
100%':[100 101.9 105.1 102.3 106.1 / using infix notation
1 1.019 1.031403 0.9733587 1.037146
```

## 5 Lists

k9 is optimized for operations on uniform lists of data. In order to take full advantage one should store data in lists and operate on them without iteration.

### 5.1 List syntax

In general, lists are created by data separated by semicolons and encased by parenthesis. Uniform lists can use a simpler syntax of spaces between elements.

```
a:1 2 3
b:(1;2;3)
a~b          / are a and b the same
1b
@a           / uniform lists are upper case value an element
`I
@a'a        / type of each element
`i`i`i
c:(1i;2f;"c";`d)
@c          / nonuniform lists are type `L
`L
@c'c
`i`f`c`s
c:1i 2f "c" `d / incorrect syntax for nonuniform list
error: type
```

### 5.2 List Indicing

Lists can be indexed by using a few notations.

```
a:2*1+!10 / 2 4 ... 20
a[10]     / out of range return null
0
a[9]      / square bracket
20
a@9       / at
20
a 9       / space
20
a(9)      / parenthesis
```

### 5.3 Updating List Elements

Lists can be updated element wise but typically one is likely to be updating many elements and there is a syntax for doing so.

```
a:2*1+!10
a
2 4 6 8 10 12 14 16 18 20
a[3]:80
```

```

a
2 4 6 80 10 12 14 16 18 20
a:@[a;0 2 4 6 8;0];a
0 4 0 80 0 12 0 16 0 20
a:@[a;1 3 5;*;100];a
0 400 0 8000 0 1200 0 16 0 20
a:@[a;!#a;;;0];a

```

List amend syntax has a few options so will be explained in more detail.

- @[list;indices;value]
- @[list;indices;identify function;value]
- @[list;indices;function;value]

The first syntax sets the list at the indices to value. The second syntax performs the same modification but explicitly lists the identity function, `!`. The third syntax is the same as the preceding but uses an arbitrary function.

Often the developer will need to determine which indices to modify and in cases where this isn't onerous it can be done in the function.

```

a:2*1+!10
@[a;&a<14;;;-3]
-3 -3 -3 -3 -3 -3 14 16 18 20
@[!10;1 3 5;;;10 20 30]
0 10 2 20 4 30 6 7 8 9
@[!10;1 3 5;;;10 20] / index and value array length mismatch
error: length
@[!10;1 3;;;10 20 30] / index and value array length mismatch
error: length

```

## 6 Dictionaries and Dictionary Functions

Simple data types can be combined into structures including Dictionaries and Tables.

### 6.1 Dictionaries

Dictionaries are key-value pairs of data. The value in the dictionary can be a single element or a list.

```
d0:`pi`e`c!3.14 2.72 3e8;d0
pi|3.14
e |2.72
c |3e+08

d1:`time`temp!(12:00 12:01 12:10;25.0 25.1 25.6);d1
time|12:00 12:01 12:10
temp|25 25.1 25.6

d2:0 10 1!37.4 46.3 0.1;d2
0|37.4
10|46.3
1|0.1
```

### 6.2 Dictionary Key !

The keys from a dictionary can be retrieved by using the `!` function.

```
!d0
`pi`e`c
!d1
`time`time
!d2
0 10 1
```

### 6.3 Dictionary as Value .

A dictionary can be returned as values using the `.` function. The function returns a list of length two. The first element is a list of the keys. The second element is a list of the values.

```
. d0
pi    e    c
3.14 2.72 3e+08

. d1
time                temp
12:00 12:01 12:10 25 25.1 25.6

. d2
0    10    1
37.4 46.3 0.1
```

One could return a specific value by indexing into a specific location. As an example in order to query the first value of the temp from d1, one would convert d1 into values (as value .), take the second index (take the value 1), take the second element (take the temp 1), and then query the first value (element 0).

```
d1
time|12:00 12:01 12:10
temp|25 25.1 25.6

(. d1)
time                temp
12:00 12:01 12:10 25 25.1 25.6

(. d1)[1]
12:00 12:01 12:10
25    25.1  25.6

(. d1)[1][1]
25 25.1 25.6
(. d1)[1][1][0]
25f
```

## 6.4 Sorting a Dictionary by Key ^

```
d0
pi|3.14
e |2.72
c |3e+08

^d0
c |3e+08
e |2.72
pi|3.14
```

## 6.5 Sorting a Dictionary by Value < and >

```
d0
pi|3.14
e |2.72
c |3e+08

<d0
e |2.72
pi|3.14
c |3e+08

>d0
c |3e+08
pi|3.14
```

```
e |2.72
```

## 6.6 Flipping a Dictionary into a Table +

This command flips a dictionary into a table but will be covered in detail in the table section. Flipping a dictionary whose values are a single element has no effect.

```
d0
pi|3.14
e |2.72
c |3e+08
```

```
+d0
pi|3.14
e |2.72
c |3e+08
```

```
do~+d0
1b
```

```
d1
time|12:00 12:01 12:10
temp|25 25.1 25.6
```

```
+d1
time  temp
-----
12:00  25
12:01  25.1
12:10  25.6
```

```
d1~+d1
0b
```

## 6.7 Functions that operate on each value in a dictionary

There are a number of simple functions on dictionaries that operate on the values. If 'f' is a function then f applied to a dictionary returns a dictionary with the same keys and the values are application of 'f'.

- -d : Negate
- d + N : Add N to d
- d - N : Subtract N from d
- d \* N : Multiple d by N
- d % N : Divide d by N
- |d : Reverse
- <d : Sort Ascending
- >d : Sort Descending

- `~d` : Not `d`
- `&d` : Given `d:x!y` repeat each `x`, `y` times, where `y` must be an integer
- `=d` : Given `d:x!y` `y!x`

Examples

```
d2
0|37.4
10|46.3
1|0.1
```

```
-d2
0|-37.4
10|-46.3
1|-0.1
```

```
d2+3
0|40.4
10|49.3
1|3.1
```

```
d2-1.7
0|35.7
10|44.6
1|-1.6
```

```
d2*10
0|374
10|463
1|1
```

```
d2%100
0|0.374
10|0.463
1|0.001
```

## 6.8 Functions that operate over values in a dictionary

There are functions on dictionaries that operate over the values. If `'f'` is a function applied to a dictionary `'d'` then `'f d'` returns a value.

- `*d` : First value

```
d0
pi|3.14
e |2.72
c |3e+08
```

```
*d0
3.14
```

## 7 More functions

This chapter includes functions that likely will be included elsewhere later.

### 7.1 parse

Parse allows one to see how a command is parsed into normal k9 form.

```

:3+2
+
3
2
t:+`a`b!(1 2;3 4)
:select from t
t
:select a from t
t
[..]
p::select a from t / store output into p
#p
2
p 0
`t
p 1
a|a
. p / value parse expression
a
-
1
2
.(`t;`a!`a) / value expression
a
-
1
2
select from t / original statement
a
-
1
2

```

Now for an example with a group clause.

```

t:+`a`b`c!(`x`y`x;0 2 10;1 1 0)
select avg:+/b%#b by a from t
a	avg
x|5
y|2

```

```

p::select avg:+/b%#b by a from t
.(#;`t;());`a!`a;`avg!(%;(+/;`b);#`b)) / parse form
#[t;();`a!`a;`avg!(%;(+/;`b);#`b)]      / functional form
a	avg
x|10
y|2
p::select avg:+/b%#b by a from t where c=1
#[t;(=;`c;1);`a!`a;`avg!(%;(+/;`b);#`b)]
a|avg
-|---
x|0
y|2

```

In the example above the parse output is reduced. In order to see the elements in the output one could manually return the values in the list, eg. `p[2;0 1 2]`.

## 8 I/O

Functions for input and output (I/O).

### 8.1 Input format values to table

This section shows you the syntax for reading in data into a table with the correct type.

```
d:,(`date`time`int`float`char`symbol)           / headers
d,:(2020.04.20;12:34:56.789;37;12.3;"hi";`bye)) /data
d
date          time          int float char  symbol
2020-04-20 12:34:56.789 37  12.3  hi    bye

`csv'd   / to csv
date,time,int,float,char,symbol
2020-04-20,12:34:56.789,37,12.3,"hi",bye

"some.csv"0:`csv'd                             / write to some.csv
0:"some.csv"                                    / read from some.csv
date,time,int,float,char,symbol
2020-04-20,12:34:56.789,37,12.3,"hi",bye

("Dtifs*";",")0:"some.csv"                     / read into table
date          time          int float char  symbol
-----
2020-04-20 12:34:56.789 37  12.3  "hi"    bye
```

### 8.2 Format to CSV/json/k $\Rightarrow$ 'csv x

Convert x to CSV/json/k format. Works on atoms, lists, and tables.

```
`csv 3 1 2
"3,1,2"
`json (3;`abc;2.3;"blue")
"[\`3\`,`abc`,2.3,`blue\`]"
`k [[i:!5;s:`a`b`c`d`e;v:5?10]
"[[i:0 1 2 3 4;s:`a`b`c`d`e;v:7 4 7 3 2]"
`csv `a`b!((1 2);(3 4))      / error as dictionary input
error: class
```

### 8.3 write line $\Rightarrow$ x 0:y

Output to x the list of strings in y. y must be a list of strings. If y is a single stream then convert to list via enlist.

```
"0:("blue";"red")           / "" represents stdout
blue
red
"0:$'("blue";"red";3)      / each element to string
```

```

blue
red
3
"some.csv"0:`,`csv 3 1 2 / will fail without enlist

```

## 8.4 read line $\Rightarrow$ 0:x

Read from file x.

```

"some.txt"0:`,`csv 3 1 2 / first write a file to some.txt
0:"some.txt"           / now read it back
3,1,2

```

## 8.5 write char $\Rightarrow$ x 1:y

Output to x the list of chars in y. y must be a list of chars. If y is a single char then convert to list via enlist.

```

"some.txt"1:"hello here\nis some text\n"
1:"some.txt"
"hello here\nis some text\n"

```

## 8.6 read char $\Rightarrow$ 1:x

Read from file x.

```

"some.txt"0:`,`csv 3 1 2 / first write a file to some.txt
1:"some.txt"           / now read it back
"3,1,2\n"

```

## 8.7 write data $\Rightarrow$ 2:

TBD

## 8.8 conn/set $\Rightarrow$ 3:

TBD

## 8.9 http/get $\Rightarrow$ 4:

TBD

## 9 Tables and kSQL

This chapter introduces k9 tables and the kSQL language to query.

### 9.1 Tables

Here is an example of a table with three columns (Day, Weather, and Temp) and three rows.

```
t: [[]Day:2020.04.10+!3;Weather:`sunny`cold`sunny;Temp:22 12 18]
t
Day          Weather Temp
-----
2020-04-10 sunny      22
2020-04-11 cold       12
2020-04-12 sunny      18
@t                                     / tables are type `A (`t is for time)
`A
+t
Day      |2020-04-10 2020-04-11 2020-04-12
Weather|sunny cold sunny
Temp   |22 12 18
```

### 9.2 A\_Tables

Here is an example of a A\_table with three columns (Day, Weather, and Temp) and three rows. One column (Day) will be add as a key.

```
t: [[Day:2020.04.10+!3]Weather:`sunny`cold`sunny;Temp:22 12 18]
t
Day	Weather Temp
2020-04-10|sunny      22
2020-04-11|cold       12
2020-04-12|sunny      18
@t                                     / A_tables have type `AA
`AA
```

### 9.3 S\_Tables

TBD

```
x:`a`b! [[]c:2 3;d:3 4;e:4 5]
x
|c d e
-|- -
a|2 3 4
b|3 4 5
```

```
@x / S_tables are type `SA
`SA
```

## 9.4 kSQL

kSQL is a powerful query language for tables.

```
select |/Temp from t where Weather=`sunny
Temp|22
```

```
select from t where Weather=`sunny
Day      Weather Temp
-----
2020-04-10 sunny    22
2020-04-12 sunny    18
```

```
select {+/x%#x}Temp from t where Weather=`sunny
Temp|20
```

```
select |/Temp from t where Weather=`sunny
Temp|22
```

## 10 System

This chapter describes the system settings and functions.

### 10.1 Display $\Rightarrow$ \k

```
m:(100 101 102;3;14 15);d:`a`b!(1 2;3 4)
\k 0
m
100 101 102
3
14 15

d
a|1 2
b|3 4

\k 1
m
(100 101 102;3;14 15)
d
[a:1 2;b:3 4]
```

### 10.2 Variables $\Rightarrow$ \v

List variables

```
a:1;b:2;c:3
\v
[v:`a`b`c]
```

### 10.3 Memory $\Rightarrow$ \w

List memory usage

```
\w
0
r:(`i$10e6)?10
\w
2097158
```

### 10.4 Timing $\Rightarrow$ \t

List time elapsed

```
\t ^(`i$1e7)?`i$1e8
360
```

## 11 X

To be sorted.

### 11.1 Errors

This section contains information on the various error messages in k9.

#### 11.1.1 error: parse

Syntax is wrong.

```
{37 . "hello"
error: parse
```

#### 11.1.2 error: value

Undefined variable is used.

```
g / assuming 'g' has not be defining in this session
error: value
```

#### 11.1.3 error: class

```
3+`b
```

#### 11.1.4 error: length

Operations on unequal length lists that require equal length.

```
(1 2 3)+(4 5)
error: length
```

#### 11.1.5 error: domain

Exhausted the number of input values

```
-12?10 / only 10 unique value exist
error: domain
```

### 11.2 `freq Histogram

Compute a histogram of a list.

```
^`freq x:100000?10
0| 9907
1| 9963
2| 9938
3|10063
4|10018
5|10007
6|10037
7|10036
8| 9907
9|10124
```

```
^#'=x / same result but slower
0| 9907
1| 9963
2| 9938
3|10063
4|10018
5|10007
6|10037
7|10036
8| 9907
9|10124
```
